LOWER URINARY TRACT SYMPTOMS INCREASE THE RISK OF FALLS IN OLDER MEN

Lori Lambert, Timothy J. Wilt 5, Howard A. Fink et al

Objective We investigated the association of lower urinary tract symptoms (LUTS) with the risk of falls in elderly community-dwelling men.

Methods We evaluated 5872 participants in the Osteoporotic Fractures study in Men, a prospective cohort study of risk factors for falls and osteoporotic fractures among community-dwelling men aged ≥65 years. The primary outcome was the 1-year cumulative incidence of falls in men with moderate or severe, vs mild LUTS at baseline, as measured by the American Urological Association Symptom Index.

Results At baseline, 3188 (54%) reported mild, 2301 (39%) moderate, and 383 (7%) severe LUTS. Compared with men who had mild symptoms, the adjusted 1-year cumulative incidence of falls was significantly higher among men with moderate or severe LUTS. The risk of at least one fall was increased by 11% among those with moderate and by 33% among those with severe LUTS. Further, those with moderate LUTS had a 21% and those with severe LUTS a 63% greater risk of at least two falls.

Conclusion Moderate and severe LUTS independently increase the 1-year risk of falls, particularly recurrent falls, in community-dwelling older men
